Working with R: learning by doing

half day workshop

Katrien Antonio

KU Leuven and UvA

2019-09-26

Who's who?

About the teacher

A collection of links:

- my personal website
- my GitHub page
- an e-book with more documentation.

Research team is here.

Practical information

Course material including

- R scripts, data, lecture sheets
- a collection of cheat sheets

are available from

https://github.com/katrienantonio/PE-working-with-R-half-day

Today's agenda

Learning outcomes

Today you will work on:

- R architecture
- R universe
- basic object types and syntax
- import/export data
- plots, plots, plots
- data structures and data wrangling
- writing functions
- linear models

You will cover examples of code¹ and work on **R challenges**.

[1] For a detailed discussion of each topic, see e-book.

Get started - explore the R architecture

What is R?

The R environment is an integrated suite of software facilities for data manipulation, calculation and graphical display.

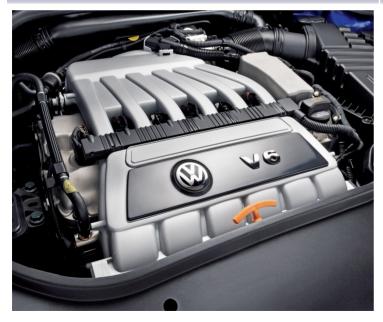

A brief history:

- R is a dialect of the S language
- R was written by Robert Gentleman and Ross Ihaka in 1992
- the R source code was first released in 1995
- in 1998, the Comprehensive R Archive Network CRAN was established
- the first official release, R version 1.0.0, dates to 2000-02-29. Currently R 3.6.1 (July, 2019)
- R is open source via the GNU General Public License.

Explore the R architecture

- R is like a car's engine
- RStudio is like a car's dashboard, an integrated development environment (IDE) for R.

R: Engine

RStudio: Dashboard

How do I code in R?

Keep in mind:

- unlike other software like Excel, STATA, or SAS, R is an interpreted language
- no point and click in R!
- you have to program in R!

R **packages** extend the functionality of R by providing additional functions, and can be downloaded for free from the internet.

R: A new phone

R Packages: Apps you can download

GET IT ON
Google Play

Download on the
App Store

Install and load an R package

The ggplot2 package is a very popular package for data visualisation.

Install the package

```
install.packages("ggplot2")
```

Load the installed package

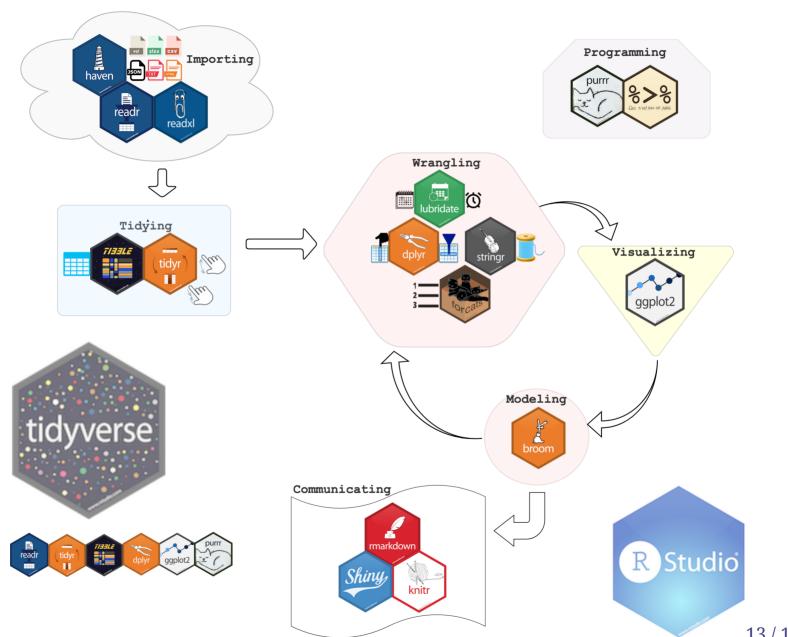

```
library(ggplot2)
```

And give it a try

```
head(diamonds)
qplot(clarity, data = diamonds, fill = cut, geom = "bar")
```

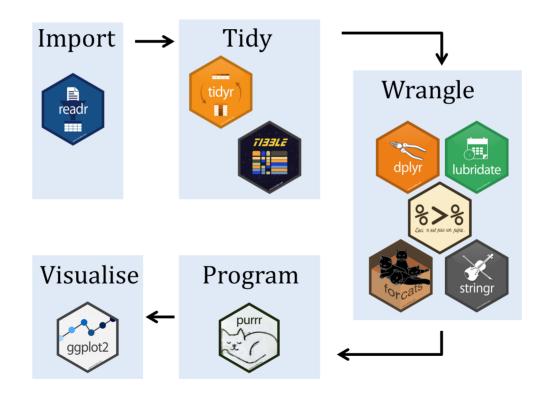

Packages are developed and maintained by R users worldwide, and shared with the R community through CRAN: now 14,963 packages online!

What's out there - the R universe

The workflow of a data scientist

The **tidyverse** is an opinionated collection of R packages designed for data science. All packages share an underlying design philosophy, grammar, and data structures.

More on: tidyverse.

Programming style

R style guide

Deciding on a **programming style** provides consistency to your code and assists in reading and writing code.

The choice of style guide is unimportant, but it is important to choose a style!

This workshop follows a set of rules roughly based on the tidyverse style guide.

R style guide

Variable names contain only **lower case** letters. If the name consists of multiple words, then these words are separated by **underscores**.

```
number_of_simulations <- 100
```

User defined functions follow the same convention as variable names, but start with a **capital** letter.

```
Multiply_by_2 <- function(x) {
  return(x * 2)
}</pre>
```

Functions from external packages usually start with a lowercase letter.

```
zero_list <- rep(0, 100)
```

Little arithmetics with R

Your first R steps

Do little arithmetics with R:

- write R code in the console
- every line of code is interpreted and executed by R
- you get a message whether or not your code was correct
- the output of your R code is then shown in the console
- use # sign to add comments, like Twitter!

Now run in the console

```
10^2 + 36
```

[1] 136

You asked and R answered!

Objects and data types in R

Variables

A basic concept in (statistical) programming is a variable.

- a variable allows you to store a value (e.g. 4) or an object (e.g. a function description) in R
- use this variable's name to easily access the value or the object that is stored within this variable.

Assign value 4 to variable a

```
a <- 4
```

and verify the variable stored

```
a
```

[1] 4

R challenge

Verify the following instructions

```
a*5
(a+10)/2
a <- a+1
```

Data types

R works with numerous data types: e.g.

- decimal values like 4.5 are called **numerics**
- natural numbers like 4 are called integers
- Boolean values (TRUE or FALSE) are called logical
- Date or POSIXct for time based variables^[1]; Date stores just a date and POSIXct stores a date and time
- text (or string) values are called characters.

[1] Both objects are actually represented as the number of days (Date) or seconds (POSIXct) since January 1, 1970.

R challenge

Run the following instructions and pay attention to the code:

```
my_numeric <- 42.5

my_character <- "some text"

my_logical <- TRUE

my_date <- as.Date("06/17/2019", "%m/%d/%Y")</pre>
```

Verify the data type of a variable with the class() function: e.g.

```
class(my_numeric)

[1] "numeric"

class(my_date)

[1] "Date"
```

Everything is an object

The fundamental design principle underlying R is "everything is an object".

Keep in mind:

- in R, an analysis is broken down into a series of steps
- intermediate results are stored in objects, with minimal output at each step (often none)
- manipulate the objects to obtain the information required
- a variable in R can take on any available data type, or hold any R object.

R challenge

Run

```
ls()
```

to list all objects stored in R's memory.

Use rm() to remove an object from R's memory, e.g.

```
rm(a)  # remove a single object
rm(my_character, my_logical)  # remove multiple objects
rm(list = c('my_date', 'my_numeric'))  # remove a list of objects
rm(list = ls())  # remove all objects
```

Basic data structures in R

Vectors

A **vector** is a simple tool to store data:

- one-dimension arrays that can hold numeric data, character data, or logical data
- you create a vector with the combine function c()
- operations are applied to each element of the vector automatically, there is no need to loop through the vector.

Here are some first examples:

```
my_vector <- c(0, 3:5, 20, 0)
my_vector[2]  # inspect entry 2 from vector my_vector
my_vector[2:3]  # inspect entries 2 and 3
length(my_vector)  # get vector length
my_family <- c("Katrien", "Jan", "Leen")
my_family</pre>
```

R challenge

You can give a name to the elements of a vector with the names() function:

```
my_vector <- c("Katrien Antonio", "teacher")
names(my_vector) <- c("Name", "Profession")
my_vector</pre>
```

```
Name Profession "Katrien Antonio" "teacher"
```

Now it's your turn!

Inspect my_vector using:

- the attributes() function
- the length() function
- the str() function

R challenge solved

[1] "Name"

```
my_vector <- c("Katrien Antonio", "teacher")</pre>
names(my_vector) <- c("Name", "Profession")</pre>
my_vector
                           Profession
              Name
                           "teacher"
"Katrien Antonio"
attributes(my_vector)
$names
[1] "Name" "Profession"
length(my_vector)
\lceil 1 \rceil 2
names(my_vector)
                "Profession"
```

Matrices

A matrix is:

- a collection of elements of the same data type (numeric, character, or logical)
- fixed number of rows and columns.

A first example

[1] 1

Data frames and tibbles

A data frame:

- is pretty much the *de facto* data structure for most tabular data
- what we use for statistics
- variables of a data set as columns and the observations as rows.

A tibble:

- a.k.a tbl
- a type of data frame common in the tidyverse
- slightly different default behaviour than data frames.

Let's explore some differences between both structures!

R challenge

Inspect a built-in data frame

```
mtcars
str(mtcars)
head(mtcars)
```

Extract a variable from a data frame and ask a summary

```
summary(mtcars$cyl) # use $ to extract variable from a data frame
```

Now inspect a tibble

```
diamonds
str(diamonds) # built-in in library ggplot2
head(diamonds)
```

Can you list some differences?

Lists

A **list** allows you to

- gather a variety of objects under one name in an ordered way
- these objects can be matrices, vectors, data frames, even other lists
- a list is some kind super data type
- you can store practically any piece of information in it!

Lists

A first example of a list:

R challenge

- 1. Create a vector fav_music with your favourite artists.
- 2. Create a vector num_records with the number of records you have in your collection of each of those artists.
- 3. Create a vector num_concerts with the number of times you attended a concert of these artists.
- 4. Put everything together in a data frame, assign the name my_music to this data frame and change the labels of the information stored in the columns to artist, records and concerts.
- 5. Extract the variable num_records from the data frame my_music.
- 6. Calculate the total number of records in your collection (for the defined set of artists).
- 7. Check the structure of the data frame, ask for a summary.

R challenge solved

Here is my solution

```
fav_music <- c("Prince", "REM", "Ryan Adams", "BLOF")
num_concerts <- c(0, 3, 1, 0)
num_records <- c(2, 7, 5, 1)
my_music <- data.frame(fav_music, num_concerts, num_records)
names(my_music) <- c("artist", "concerts", "records")</pre>
```

R challenge solved

```
summary(my_music)
##
   artist
                  concerts
                              records
##
  BLOF :1 Min. :0.0
                            Min. :1.00
## Prince :1 1st Qu.:0.0 1st Qu.:1.75
       :1 Median :0.5 Median :3.50
##
   REM
   Ryan Adams:1 Mean :1.0
                            Mean :3.75
##
##

## [1] 2 7 5 1
sum(my_music$records)
## [1] 15
```

Getting started with data in R

Importing data in R

Some useful instructions regarding path names:

get your working directory

```
getwd()
```

• specify a path name, with forward slash or double back slash

```
path <- file.path("C:/Users/u0043788/Dropbox/PE Programming in R for
setwd(path)
```

• use a relative path

```
path_pools <- file.path("./data/swimming_pools.csv")</pre>
```

or

```
path_pools <- file.path("../data/swimming_pools.csv")</pre>
```

Importing data in R

Some useful instructions regarding path names:

• extract the directory of the current active file in RStudio via the package rstudioapi

```
path <- dirname(rstudioapi::getActiveDocumentContext()$path)
setwd(path)</pre>
```

and then you'll work with

```
path_pools <- file.path("../data/swimming_pools.csv")</pre>
```

Import a .txt file

read.table() is the most basic importing function.

You can specify tons of different arguments in this function.

or like this

What happened?

Import a .csv file

read.csv() is the basic importing function.

Here is an example:

- load a data set on swimming pools in Brisbane
- column names in the first row; a comma to separate values within rows

```
path_pools <- file.path("../data/swimming_pools.csv")
pools <- read.csv(path_pools)
str(pools)</pre>
```

But, what happens?

With stringsAsFactors you can tell R whether it should convert strings in the flat file to factors.

```
pools <- read.csv(path_pools, stringsAsFactors = FALSE)
str(pools)</pre>
```

Useful packages for data import

The readr package

The goal of readr is:

• to provide a fast and friendly way to read rectangular data (like csv, tsv, and fwf).

To read a rectangular dataset with readr you combine two pieces:

- a function that parses the overall file
- a column specification.

The column specification describes how each column should be converted from a character vector to the most appropriate data type, and in most cases it's not necessary because readr will guess it for you automatically.

The readr package

readr supports seven file formats with seven read_ functions:

- read_csv(): comma separated (CSV) files
- read_tsv(): tab separated files
- read_delim(): general delimited files
- read_fwf(): fixed width files
- read_table(): tabular files where columns are separated by white-space
- read_log(): web log files.

More details on https://readr.tidyverse.org/.

Import a .xlsx file

The readxl package makes it easy to get Excel data into R:

- no external dependencies, so it's easy to install and use
- designed to work with tabular data.

```
library(readxl)
path_urbanpop <- file.path("../data/urbanpop.xlsx")
excel_sheets(path_urbanpop) # list sheet names with `excel_sheets()`</pre>
```

Specify a worksheet by name or number, e.g.

```
pop_1 <- read_excel(path_urbanpop, sheet = 1)
pop_2 <- read_excel(path_urbanpop, sheet = 2)</pre>
```

inspect and re-combine

```
str(pop_1)
pop_list <- list(pop_1, pop_2)</pre>
```

Import other data formats

The haven package enables R to read and write various data formats used by other statistical packages.

It supports:

- **SAS**: read_sas() reads .sas7bdat and .sas7bcat files and read_xpt() reads SAS transport files (version 5 and version 8). write_sas() writes .sas7bdat files.
- **SPSS**: read_sav() reads .sav files and read_por() reads the older .por files. write_sav() writes .sav files.
- **Stata**: read_dta() reads .dta files (up to version 15). write_dta() writes .dta files (versions 8-15).

R challenge

Load the following data sets, available in the course material:

- the Danish fire insurance losses, stored in danish.txt
- the severity data set, stored in severity.sas7bdat
- the policy data set, stored in PolicyData.csv, wih variables separated by a semicolon.

R challenge solved

Import the Danish fire insurance losses

```
path <- file.path('../data')
path.danish <- file.path(path, "danish.txt")
danish <- read.table(path.danish, header = TRUE)
danish$Date <- as.Date(danish$Date, "%m/%d/%Y")
str(danish)

## 'data.frame': 2167 obs. of 2 variables:
## $ Date : Date, format: "1980-01-03" "1980-01-04" ...
## $ Loss.in.DKM: num 1.68 2.09 1.73 1.78 4.61 ...</pre>
```

Import the severity data set

```
library(haven)
severity <- read_sas('../data/severity.sas7bdat')
str(severity)</pre>
```

R challenge solved

Import the policy data set

```
str(policy_data)
## 'data.frame': 39075 obs. of 22 variables:
   $ numeropol : int 3 3 6 6 6 6 6 6 6 6 ...
##
   $ debut_pol : Factor w/ 2956 levels "1/01/1996","1/01/1997",..: 554
##
## $ fin_pol : Factor w/ 3093 levels "1/01/1996","1/01/1997",..: 1652
   $ freq_paiement : Factor w/ 2 levels "annuel", "mensuel": 2 2 1 1 1 1 1 1
##
##
   $ langue
             : Factor w/ 2 levels "A", "F": 2 2 1 1 1 1 1 1 1 1 ...
##
   $ type_prof : Factor w/ 10 levels "Actuaire", "Autre", ...: 10 10 10 10
##
   $ alimentation : Factor w/ 3 levels "Carnivore","Végétalien",..: 3 3 1
   $ type_territoire: Factor w/ 3 levels "Rural", "Semi-urbain",..: 3 3 3 3
##
##
   $ utilisation
                    : Factor w/ 3 levels "Loisir", "Travail-occasionnel",...
   $ presence_alarme: Factor w/ 2 levels "non","oui": 1 1 2 2 2 2 2 2 2 2 ...
##
   $ marque_voiture : Factor w/ 31 levels "ALFAROMEO", "AUDI", ...: 30 30 19 19
##
                    : Factor w/ 2 levels "F", "M": 1 1 2 2 2 2 2 2 2 2 ...
##
   $ sexe
                    : num NA NA 280 NA NA ...
##
   $ cout1
##
   $ cout2
                    : num NA NA NA NA NA NA NA NA NA ...
##
                    : num NA NA NA NA NA NA NA NA NA ...
   $ cout3
                    : num NA NA NA NA NA NA NA NA NA ...
##
   $ cout4
                                                                   51 / 141
```

policy_data <- read.csv(file = '../data/PolicyData.csv', sep = ';')</pre>

Exploratory data analysis

A numeric variable

[1] 26.41032

You first explore a **numeric** variable:

load the CPS1985 data set and inspect the wage variable

```
summary(cps_1985$wage) # get a summary
## Min. 1st Ou. Median Mean 3rd Ou. Max.
##
  1.000 5.250 7.780 9.024 11.250 44.500
is.numeric(cps_1985$wage) # check if variable is numeric
## [1] TRUE
mean(cps_1985$wage)
                            # get mean
## [1] 9.024064
var(cps_1985$wage)
                            # get variance
```

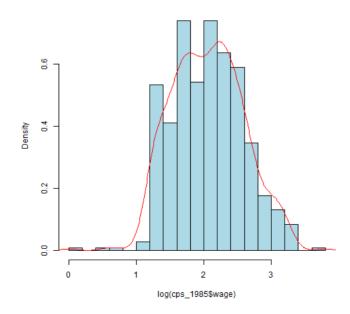

A numeric variable

You first explore a **numeric** variable:

visualize the wage distribution

```
hist(log(cps_1985$wage), freq = FALSE, nclass = 20, col = "light bluelines(density(log(cps_1985$wage)), col = "red")
```

Histogram of log(cps_1985\$wage)

A factor variable

You now explore the occupation variable

```
summary(cps_1985$occupation)

management office sales services technical worker
55 97 38 83 105 156
```

change the names of some of the levels

```
levels(cps_1985$occupation)[c(1, 5)] <- c("mgmt", "techn")
summary(cps_1985$occupation)</pre>
```

```
mgmt office sales services techn worker 55 97 38 83 105 156
```

A factor variable

You now explore the occupation variable:

visualize the distribution

```
tab <- table(cps_1985$occupation)
prop.table(tab)

##

##

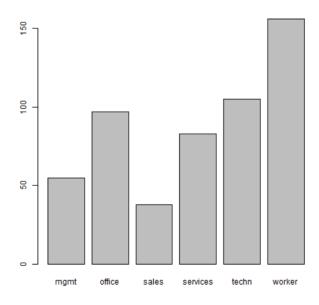

## mgmt office sales services techn worker
## 0.10299625 0.18164794 0.07116105 0.15543071 0.19662921 0.29213483</pre>
```

A factor variable

You now explore the occupation variable:

• visualize the distribution

barplot(tab)

Two factor variables

You now explore the factor variables gender and occupation.

```
Use prop.table()
```

```
# attach the data set to avoid use of
attach(cps_1985)
table(gender, occupation)
                                 # no name df$name var necessary
       occupation
gender
        mgmt office sales services techn worker
 female
          21
                 76
                       17
                                49
                                      52
                                            30
 male
          34
                 21
                       21
                                      53
                                           126
                                34
prop.table(table(gender, occupation))
```

```
occupation
```

```
gender mgmt office sales services techn worker female 0.03932584 0.14232210 0.03183521 0.09176030 0.09737828 0.05617978 male 0.06367041 0.03932584 0.03932584 0.06367041 0.09925094 0.23595506
```

```
detach(cps_1985) # now detach when work is done
```

Two factor variables

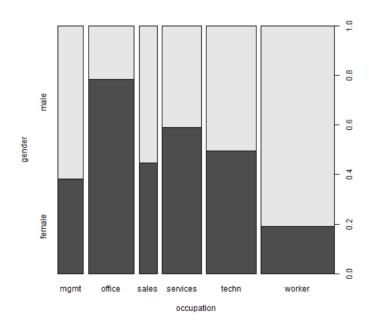

```
Now try prop.table(table(gender, occupation), 2). What happens?
```

Two factor variables

You now explore the factor variables gender and occupation.

Do a mosaic plot

```
plot(gender ~ occupation, data = cps_1985)
```

A factor and a numeric variable

You now explore the factor gender and the numeric variable wage.

```
tapply(wage, gender, mean)

## female male
## 7.878857 9.994913

tapply(log(wage), list(gender, occupation), mean)

## mgmt office sales services techn worker
## female 2.229256 1.931128 1.579409 1.701674 2.307509 1.667887
## male 2.447476 1.955284 2.141071 1.829568 2.446640 2.100418
```

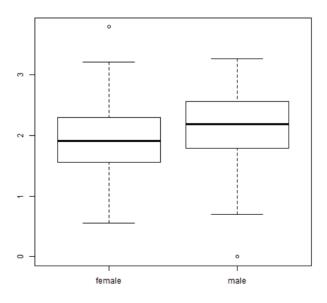

So, tapply subsets the wage by gender (or: gender and occupation) and then applies the function mean to each subset.

A factor and a numeric variable

You now explore a factor variable and a numeric variable.

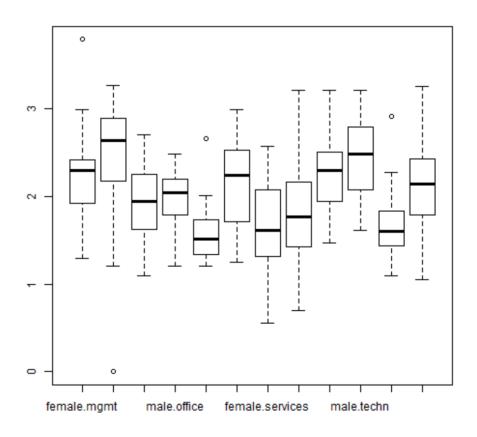

Visualize the distribution of wage per gender

```
boxplot(log(wage) ~ gender, data = cps_1985)
```

Now try with

```
boxplot(log(wage) ~ gender + occupation, data = cps_1985)
```

Data visualisation in R

Basic plot instructions

Your starting point is the construction of a **scatterplot**:

- load the journals.txt data set and save as journals data frame
- work through the following instructions

```
journals$cite_price <- journals$price/journals$citations
plot(log(cite_price) ~ log(subs), data = journals)
rug(log(journals$subs))
rug(log(journals$cite_price), side = 2)</pre>
```

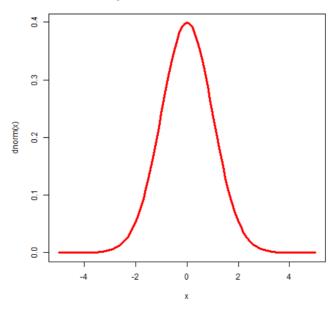

and adjust the plotting instructions

Basic plot instructions

The curve() function draws a curve corresponding to a function over the interval [from, to].

```
curve(dnorm, from = -5, to = 5, col = "red", lwd = 3,
    main = "Density of the standard normal distribution")
```

Density of the standard normal distribution

The aim of the ggplot2 package is to create elegant data visualisations using the grammar of graphics.

Here are the basic steps:

- begin a plot with the function ggplot() creating a coordinate system that you can add layers to
- the first argument of ggplot() is the dataset to use in the graph

Thus

```
library(ggplot2)
ggplot(data = mpg)
ggplot(mpg)
```

creates an empty graph.

You complete your graph by adding one or more **layers** to ggplot().

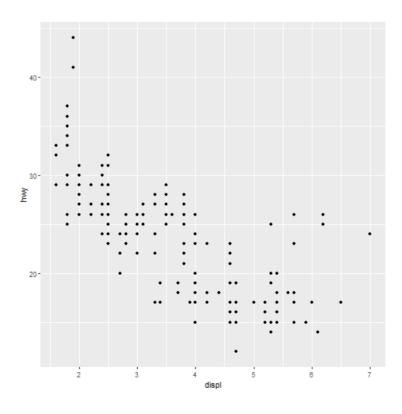

For example:

- geom_point() adds a layer of points to your plot, which creates a scatterplot
- geom_smooth() adds a smooth line
- geom_bar a bar plot.

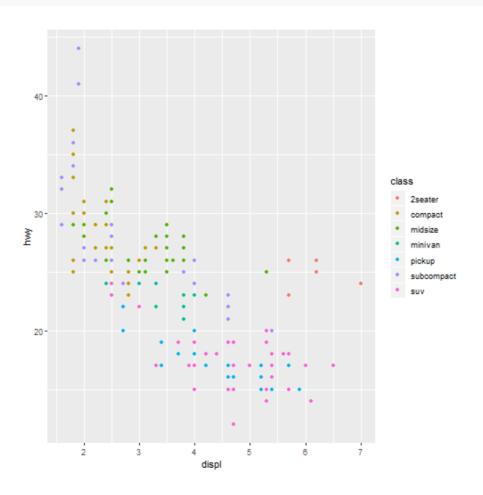

Each geom function in ggplot2 takes a mapping argument:

- how variables in your dataset are mapped to visual properties
- always paired with aes() and the x and y arguments of aes() specify which variables to map to the x and y axes.

```
library(ggplot2)
ggplot(data = mpg) + geom_point(mapping = aes(x = displ, y = hwy))
```

```
ggplot(data = mpg) + geom_point(aes(x = displ, y = hwy, color = class)
```

Compare the following set of instructions:

• inside of aesthetics

```
ggplot(mpg) + geom_point(aes(x = displ, y = hwy, color = class))
```

• inside of aesthetics, not mapped to a variable

```
ggplot(mpg) + geom_point(aes(x = displ, y = hwy, color = "blue"))
```

outside of aesthetics

```
ggplot(mpg) + geom_point(aes(x = displ, y = hwy), color = "blue")
```

Now play with different geoms:

a scatterplot

```
ggplot(mpg) + geom_point(mapping = aes(x = class, y = hwy))
```

a boxplot

```
ggplot(data = mpg) +
geom_boxplot(mapping = aes(x = class, y = hwy))
```

• a histogram

```
ggplot(data = mpg) +
geom_histogram(mapping = aes(x = hwy))
```

• a density

```
ggplot(data = mpg) +
geom_density(mapping = aes(x = hwy))
```

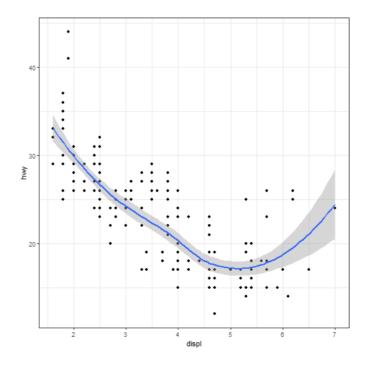

Now you will add multiple geoms to the same plot.

Predict what the following code does:

```
ggplot(data = mpg) +
  geom_point(mapping = aes(x = displ, y = hwy)) +
  geom_smooth(mapping = aes(x = displ, y = hwy))
```

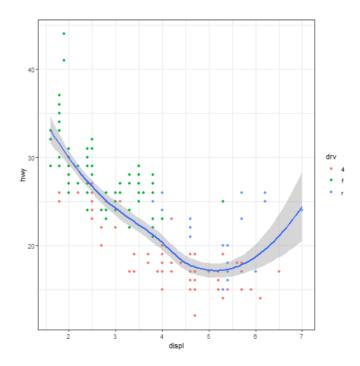

Mappings and data can be specified **global** (in ggplot()) or local.

```
ggplot(data = mpg, mapping = aes(x = displ, y = hwy)) +
  geom_point() +
  geom_smooth() + theme_bw() # adjust theme
```

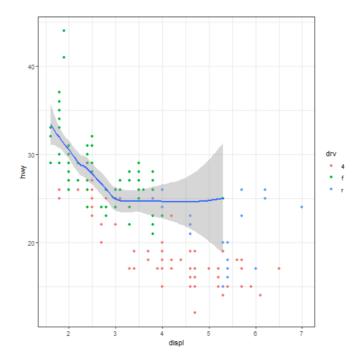

Mappings and data can be specified global or **local**.

```
ggplot(data = mpg, mapping = aes(x = displ, y = hwy)) +
  geom_point(mapping = aes(color = drv)) +
  geom_smooth() + theme_bw()
```

Mappings and data can be specified global or **local**.

```
library(dplyr)
ggplot(data = mpg, mapping = aes(x = displ, y = hwy)) +
  geom_point(mapping = aes(color = drv)) +
  geom_smooth(data = filter(mpg, drv == "f")) + theme_bw()
```

R challenge

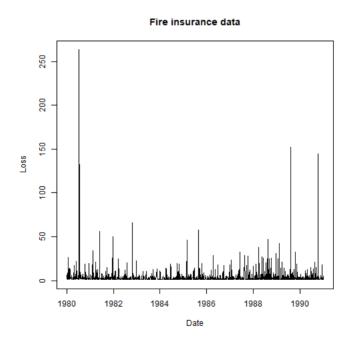

Use the Danish fire insurance losses. Plot the arrival of losses over time.

- 1. Use type= "l" for a line plot, label the x and y-axis, and give the plot a title using main.
- 2. Do the same with instructions from ggplot2. Use geom_line() to create the line plot.

R challenge solved

A classic plot of the Danish fire insurance losses

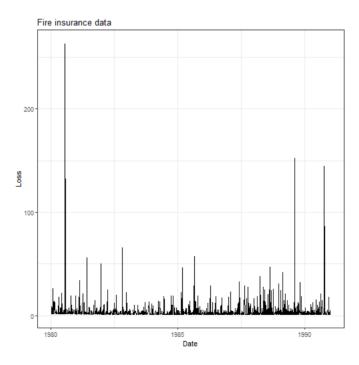

```
plot(danish$Date, danish$Loss.in.DKM, type = "l", xlab = "Date", ylak
    main = "Fire insurance data")
```

R challenge solved

With ggplot2

```
ggplot(danish, aes(x = Date, y = Loss.in.DKM)) +
   geom_line() + theme_bw() +
   labs(title = "Fire insurance data", x = "Date", y = "Loss")
```

R challenge

- 1. Use the data set car_price.csv available in the documentation. Import the data in R.
- 2. Explore the data.
- 3. Make a scatterplot of price versus income, use basic plotting instructions and use ggplot2.
- 4. Add a smooth line to each of the plots (using lines to add a line to an existing plot and lowess to do scatterplot smoothing and using geom_smooth in the ggplot2 grammar).

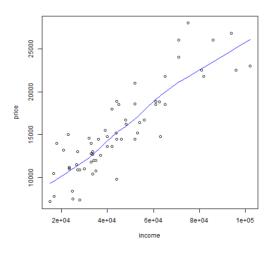

R challenge solved

Load the data

```
car_price <- read.csv("../data/car_price.csv")</pre>
```

Do a traditional plot

```
plot(price ~ income, data = car_price)
lines(lowess(car_price$income, car_price$price), col = "blue")
```

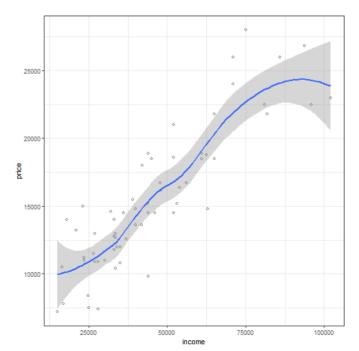

R challenge solved

With ggplot

```
ggplot(car_price, aes(x = income, y = price)) +
  geom_point(shape = 1, alpha = 1/2) +
  geom_smooth() + theme_bw()
```

 $geom_smooth()$ using method = 'loess' and formula 'y ~ x'

Data wrangling in R

Three directions for data wrangling

Three lines of work are available:

- the basic R instructions (e.g. using subset, aggregate)
- the RStudio line offering the packages from the tidyverse, including the dplyr package
- the data.table line developed by Matt Dowle, see e.g. DataCamp's course on data.table.

The latter two:

- offer advanced, and fast, data handling with large R objects and lots of flexibility
- have a very specific syntax, with a demanding learning curve.

This tutorial will mainly explore the tidyverse direction.

The basic split-apply-combine strategy

We first cover some basic R instructions, before diving into the tidyverse.

Use the diamonds data set (from the ggplot2 package) and subset

```
subset(diamonds, cut == "Ideal")
my_subset <- diamonds[, c("carat", "cut", "color", "clarity")]</pre>
```

Calculate a new variable

```
diamonds$price_per_carat <- diamonds$price/diamonds$carat
```

Calculate average price per each type of cut

```
aggregate(price ~ cut, diamonds, mean)
```

or

```
aggregate(price ~ cut + color, diamonds, mean)
```

Entering the tidyverse

The tidyverse is a collection of R packages sharing the same design philosphy.

require(tidyverse) loads the 8 core packages:

- ggplot2
- readr
- stringr
- dplyr
- purrr
- forcats
- tidyr
- tibble

install.package(tidyverse) installs many other packages, including:

- lubridate
- readxl

Today you will use 5-6 packages from the tidyverse!

A tibble instead of a data.frame

Within the tidyverse tibbles are a modern take on data frames:

- keep the features that have stood the test of time
- drop the features that used to be convenient but are now frustrating.

You can use:

- tibble() to create a new tibble
- as_tibble() transforms an object (e.g. a data frame) into a tibble.

R challenge

str(mtcars)

Transform mtcars into a tibble and inspect

```
library(tibble)
    as_tibble(mtcars)
                       A tibble: 32 \times 11

Pipes in R

In R, the pipe operator is %>%.

You can think of this operator as being similar to the + in a ggplot2 statement.

It takes the output of one statement and makes it the input of the next statement.

When describing it, you can think of it as a "THEN".

A first example:

- take the diamonds data (from the ggplot2 package)
- then subset

```
diamonds %>% filter(cut == "Ideal")
```

Data manipulation verbs

The dplyr package holds many useful data manipulation verbs:

- mutate() adds new variables that are functions of existing variables
- select() picks variables based on their names
- filter() picks cases based on their values
- summarise() reduces multiple values down to a single summary
- arrange() changes the ordering of the rows.

These all combine naturally with group_by() which allows you to perform any operation "by group".

filter()

Extract rows that meet logical criteria.

- inspect the diamonds data set
- filter observations with cut equal to Ideal

```
filter(diamonds, cut == "Ideal")
## # A tibble: 21,551 x 10
```

```
carat cut color clarity depth table price

```

filter()

Here is an overview of logical tests

x < y	Less than
x > y	Greater than
× == y	Equal to
x <= y	Less than or equal to
× >= y	Greater than or equal to
× != y	Not equal to
x %in% y	Group membership
is.na(x)	Is NA
!is.na(x)	Is not NA

mutate()

Create new columns.

- inspect the diamonds data set
- create a new variable price_per_carat

```
mutate(diamonds, price_per_carat = price/carat)
```

```

```

Multistep operations

Use the %>% for multistep operations.

Passes result on left into first argument of function on right.

```
diamonds %>% mutate(price_per_carat = price/carat) %>%
  filter(price_per_carat > 1500)
```

```

```

summarise()

Compute table of summaries.

- inspect the diamonds data set
- calculate mean and standard deviation of price

```
diamonds %>% summarise(mean = mean(price), std_dev = sd(price))

## # A tibble: 1 x 2

## mean std_dev

## <dbl> <dbl>
## 1 3933. 3989.
```

group_by()

Groups cases by common values of one or more columns.

- inspect the diamonds data set
- calculate mean and standard deviation of price by level of cut

R challenge

- 1. Load the data Parade2005.txt.
- 2. Determine the mean earnings in California.
- 3. Determine the number of individuals residing in Idaho.
- 4. Determine the mean and the median earnings of celebrities.

R challenge solved

R challenge solved - cont.

We can solve the same challenge with **basic** R instructions.

```
CA_data <- subset(parade_2005, state == "CA")
mean(CA_data$earnings)</pre>
```

or do

```
tapply(earnings, state, mean)
aggregate(earnings ~ state, parade_2005, mean)
```

and for the number of inhabitants in Idaho

```
d <- aggregate(earnings ~ state , parade_2005, length)
d[d$state == "ID", ]</pre>
```

Join operations

A **join** operation in database terminology is a merging of two data frames.

There are 4 types of joins:

- **Inner join** (or join): retain just the rows each table that match the condition
- **Left outer join** (or left join): retain all rows in the first table, and just the rows in the second table that match the condition
- **Right outer join** (or right join): retain just the rows in the first table that match the condition, and all rows in the second table
- Full outer join (or full join): retain all rows in both tables

Column values that cannot be filled in are assigned NA values

Join operations

We create a toy data set with policyholders¹:

inner_join()

We join tab1 and tab2 by name, but keep only customers in intersection:

left_join()

We join tab_1 and tab_2 by name, but keep all customers from tab_1:

right_join()

We join tab_1 and tab_2 by name, but keep all customers from tab_2:

full_join()

Finally, suppose we want to join tab_1 and tab_2 by name, and keep all customers from both:

Conditionals and control flow

Conditionals and control flow

You'll first learn about relational operators to see how R objects compare.

Make sure not to mix up == and =, where the latter is used for assignment and the former checks equality.

```
3 == (2 + 1)
"intermediate" != "r"
(1 + 2) > 4
katrien <- c(19, 22, 4, 5, 7)
katrien > 5
```

Logical operators

Now you'll learn about logical operators to combine logicals

```
TRUE & TRUE

FALSE | TRUE

5 <= 5 & 2 < 3

3 < 4 | 7 < 6
```

applied to vectors

```
katrien <- c(19, 22, 4, 5, 7)
jan <- c(34, 55, 76, 25, 4)
katrien > 5 & jan <= 30
```

```
## [1] FALSE FALSE FALSE TRUE
```

The! operator reverses the result of a logical value.

```
!TRUE
```

```
## [1] FALSE
```

Conditionals

Time to check the if statement in R.

```
num_attendees <- 30
if (num_attendees > 5) {
   print("You're popular!")
}

[1] "You're popular!"
and the if else
```

```
num_attendees <- 5
if (num_attendees > 5) {
  print("You're popular!")
}else{
  print("You are not so popular!")
}
```

[1] "You are not so popular!"

Conditionals

We can use elseif() arbitrarily many times following an if() statement

```
if (x^2 < 1) {
    x^2
} else if (x >= 1) {
    2*x-1
} else {
    -2*x-1
}
```

[1] 3

For quick decision making use ifelse()

```
ifelse(x > 0, x, -x)
```

[1] 2

Conditionals

Instead of an if() statement followed by elseif() statements (and perhaps a final else), we can use switch().

We pass a variable to select on, then a value for each option

[1] "I don't understand"

Loops

You'll start with a while loop.

```
todo <- 64
while (todo > 30) {
  print("Work harder")
  todo <- todo - 7
}

[1] "Work harder"
[1] "Work harder"
[1] "Work harder"
[1] "Work harder"
[1] "Work harder"</pre>
```

Loops in R

Now the for loop in R.

```
primes <- c(2, 3, 5, 7, 11, 13)

# loop version 1
for (p in primes) {
    print(p)
}
# loop version 2
for (i in 1:length(primes)) {
    print(primes[i])
}</pre>
```

Writing functions

Write your own function

Creating a function in R is basically the assignment of a function object to a variable.

```
My_sqrt <- function(x) {
   sqrt(x)
}

# use the function
My_sqrt(12)</pre>
```

[1] 3.464102

With no explicit return() statement, the default is just to return whatever is on the last line.

Write your own function

You can define default argument values in your own R functions.

Here you see an example:

```
My_sqrt <- function(x, print_info = TRUE) {</pre>
  y \leftarrow sqrt(x)
  if (print_info) {
     print(paste("sqrt", x, "equals", y))
   return(y)
# some calls of the function
My_sqrt(16)
[1] "sqrt 16 equals 4"
\lceil 1 \rceil 4
My_sqrt(16, FALSE)
```

[1] 4

Vectorized thinking

R works in a vectorized way.

Check this by calling the function My_sqrt on an input vector.

What the function can see and do

Some things to keep in mind:

- each function has its own environment
- names here override names in the global environment
- internal environment starts with the named arguments
- assignments inside the function only change the internal environment
- names undefined in the function are looked for in the global environment.

R challenge

- 1. Create a function that will return the sum of 2 integers
- 2. Create a function that given a vector and an integer will return how many times the integer appears inside the vector.
- 3. Create a function that given a vector will print by default the mean and the standard deviation, it will optionally also print the median. Use an instruction like the one printed below for the print messages.
- 4. Adjust the function created in 3. so that it returns a list with the mean, median and standard deviation.

```
cat("Mean is:", mean, ", SD is:", stdv, "\n")
```

```
My_sum <- function (x, y) {
   r <- x + y
   r
}
My_sum(5, 10)</pre>
```

[1] 15

```
My_count <- function (v, x) {
   count <- 0
   for (i in 1:length(v)) {
      if (v[i] == x) {
        count <- count + 1
      }
   }
   count
}</pre>
```

[1] 100

```
My_mean_SD <- function(x, med = FALSE) {
    mean <- round(mean(x), 1)
    stdv <- round(sd(x), 1)
    cat("Mean is:", mean, ", SD is:", stdv, "\n")

if(med) {
    median <- median(x)
    cat("Median is:", median , "\n")
    }
}

My_mean_SD(1:10, med=TRUE)</pre>
```

```
Mean is: 5.5 , SD is: 3 Median is: 5.5
```

```
My_mean_SD <- function(x, med = FALSE) {
  mean <- round(mean(x), 1)
  stdv <- round(sd(x), 1)
  if(!med) {
  return(list(mean = mean, stdev = stdv))
  }
  else {
    median <- median(x)
    return(list(mean = mean, stdev = stdv, median = median))
  }
}
My_mean_SD(1:10, med = TRUE)</pre>
```

```
$mean
[1] 5.5
$stdev
[1] 3
$median
[1] 5.5
```

Working with probability distributions

Probability distributions

R has 4 crucial functions for many standard distributions

- density: e.g. dexp, dgamma, dlnorm
- quantile: e.g. qexp, qgamma, qlnorm
- cdf: e.g. pexp, pgamma, plnorm
- simulation: e.g. rexp, rgamma, rlnorm

The **parameters** of the distribution are then specified in the arguments of these functions.

Discrete distributions

You generate n_sim observations from a BIN(n, p) distribution:

```
n_sim <- 10000 # number of generated draws
p <- 0.3 # prob of success
n <- 6 # number of experiments in BIN

data_binom <- rbinom(n_sim, n, p)</pre>
```

Calculate empirical mean and variance

```
mean(data_binom) # empirical mean

## [1] 1.8131

var(data_binom) # empirical variance

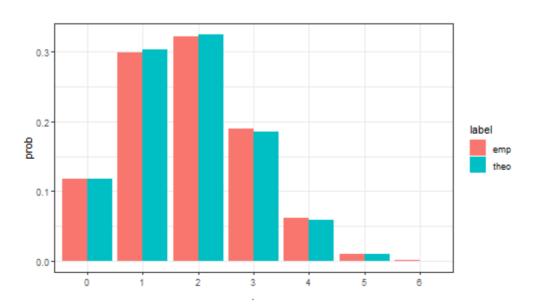

## [1] 1.277096
```

Now compare empirical mean/variance with their theoretical counterparts.

Discrete distributions

Now you want to visualize the empirical cdf and pf.

```
x <- sort(unique(data_binom))
emp_prob <- data_binom %>% table() %>% as.data.frame() %>% mutate(labtheo_prob <- data_binom %>% table() %>% as.data.frame() %>% mutate(labtheo_prob <- bind_rows(theo_prob, emp_prob) # or use 'rbind'
df$label <- as.factor(df$label)
ggplot(df, aes(., prob)) + theme_bw() + geom_col(aes(fill = label), prob)</pre>
```

Continuous distributions

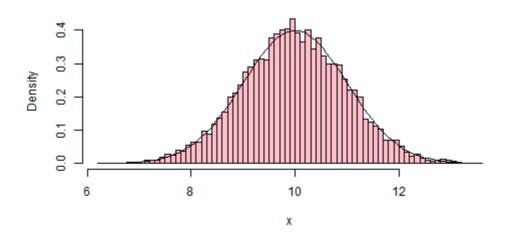

Working with the normal distribution

```
# evaluate cdf of N(0,1) in 0
pnorm(0, mean = 0, sd = 1)
## [1] 0.5
pnorm(0, 0, 1) # shorter
## [1] 0.5
# 95% quantile of N(0,1)
qnorm(0.95, mean = 0, sd = 1)
## [1] 1.644854
# a set of quantiles
qnorm(c(0.025, 0.05, 0.5, 0.95, 0.975), 0, 1)
## [1] -1.959964 -1.644854 0.000000 1.644854 1.959964
```

Continuous distributions

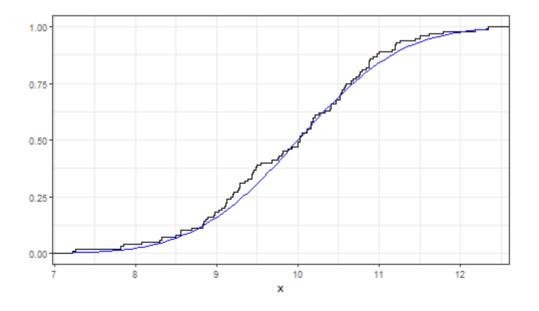

Working with the normal distribution

```
x <- rnorm(10000, mean = 10, sd = 1)
hist(x, probability = TRUE, nclass = 55, col = "pink", main = " ")
curve(dnorm(x, mean = 10, sd = 1), xlim = range(x), col = "black", ac</pre>
```

R challenge

```
x <- rnorm(100, mean = 10, sd = 1)
df <- data.frame(x = x)
ggplot(df, aes(x)) + stat_ecdf(geom = "step") + theme_bw() + ylab("")
  stat_function(fun = pnorm, args = list(mean = 10, sd = 1), col = "k")</pre>
```

Fitting models to data

Analyzing credit card applicants' data

Your journey as a model builder in R will start from studying linear models and the use of the lm function.

Hereto:

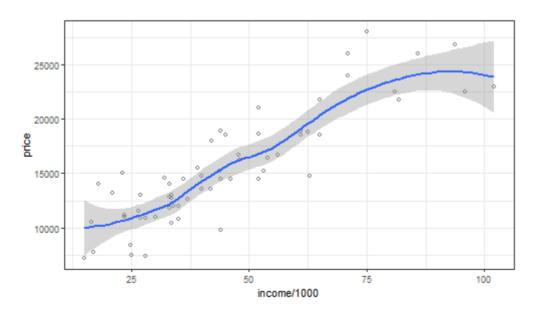

- you analyze Ford dealership data as registered in Milwaukee, September/October 1990
- data on 62 credit card applicants are available, including the car purchase price Y and the applicant's annual income x
- data are in the .csv file car_price.

Explore the data

You inspect the data with a scatterplot of income versus price:

```
ggplot(car_price, aes(x = income/1000, y = price)) +
  theme_bw() +
  geom_point(shape = 1, alpha = 1/2) +
  geom_smooth()
```

`geom_smooth()` using method = 'loess' and formula 'y ~ x'

A simple linear regression fit

You will now fit a simple regression model with income as predictor to purchase price. That is:

$$Y_i = \beta_0 + \beta_1 \cdot x_i + \epsilon_i,$$

where Y_i is the car price for observation i, x_i the corresponding income and ϵ_i an error term.

 β_0 is the intercept and β_1 the slope.

Im()

You assign the output of the lm function to the object lm_car

```
lm_car <- lm(price ~ income, data = car_price)</pre>
```

Now you inspect the results:

```
class(lm_car) # object class
summary(lm_car) # get a summary
# check attributes of object 'lm_car'
names(lm_car)
# some useful stuff: 'coefficients', 'residuals', 'fitted.values', 'r
lm_car$coef
lm_car$residuals
lm_car$fitted.values
```

Utility functions

Linear models in R come with a bunch of utility functions:

- coef() for retrieving coefficients
- fitted() for fitted values
- residuals() for residuals
- summary(), plot(), predict() and so on.

Once you master the utility functions, you'll be able to retrieve coefficients, fitted values, make predictions, etc., in the same way for model objects returned by glm(), gam(), and many others.

Visualize the lm() fit

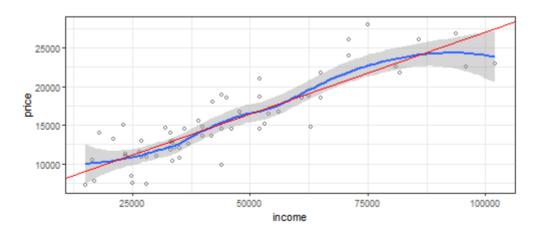

To visualize this linear model fit you can use the built-in plot function, applied to object lm_car

```
plot(lm_car)
```

Visualize the lm() fit

Or you can create your own plot

```
ggplot(car_price, aes(x = income, y = price)) +
   theme_bw() +
   geom_point(shape = 1, alpha = 1/2) +
   geom_smooth() +
   geom_abline(intercept = lm_car$coef[1], slope = lm_car$coef[2], cold
## `geom_smooth()` using method = 'loess' and formula 'y ~ x'
```

predict()

Making predictions for new applicants:

```
new <- data.frame(income = 60000) # set up a new data frame
new_pred <- predict(lm_car, newdata = new) # call predict with new data
new_pred</pre>
## 1
```

1 ## 18545.77

R challenge

- 1. Load the pollution.csv data set.
- 2. Read the data description here.
- 3. Create data frames of related covariates and visualize. Use code printed below.
- 4. Build a linear regression model to explain mort as a function of so2 and educ. Inspect the model and fit.

```
mort_poll_1 <- data.frame(mort, prec, jant, jult, humid)
mort_poll_2 <- data.frame(mort, ovr65, popn, educ, hous, dens, nonw,
mort_poll_3 <- data.frame(mort, hc, nox, so2)

pairs(mort_poll_1, cex=1, pch=19)</pre>
```

Thanks!
